(54) Scratch protection for direct contact sensors

(57) In capacitive sensor circuits where physical contact is required and excess pressure may be inadvertently applied to the sensor surface, aluminum is not sufficiently hard to provide "scratch" protection and may delaminate, causing circuit failure, even if passivation integrity remains intact. Because hard passivation layers alone provide insufficient scratch resistance, at least the capacitive electrodes and preferably all metallization levels within the sensor circuit in the region of the

capacitive electrodes between the surface and the active regions of the substrate are formed of a conductive material having a hardness greater than that of aluminum. The selected conductive material is employed for each metallization level between the surface and the active regions, including contacts and vias, landing pads, interconnects, capacitive electrodes, and electrostatic discharge protection lines.

FIG. 3

EP 1 073 117 A2

Description

[0001] The present invention relates generally to scratch protection for integrated sensor circuits, and more specifically to improvement of scratch protection in capacitive sensor circuits through selection of metallization materials.

[0002] Fingerprint acquisition circuits employ arrays of sensors coated with a dielectric onto which the finger is placed with the epidermis in contact with the dielectric. The ridges and grooves on the epidermal layer of the finger are then detected by the sensors, which transmit signals representative of the detected pattern. Although various sensors are possible (e.g., resistive, etc.), capacitive sensors have been found to provide the best performance. Since capacitance between two capacitive plates is inversely proportional to the distance between the plates, using the contacting dermal tissue itself as one capacitor plate and the sensor electrode as the other and then determining capacitance for each sensor electrode in the array, it is possible to locate the ridges and grooves of the fingerprint.

[0003] Such capacitive sensors cannot be mechanically protected because physical contact on the surface of the integrated circuit with the finger is necessary. However, some scratch resistance protection for the capacitive sensor electrodes is required to prevent "scratch" damage to the sensor electrodes. Such damage typically results from undue (and unnecessary) pressure on the surface of the integrated circuit, alone or in combination with some sharp edge or protrusion such as a callous or scar, fingernail, dust or dirt particle, etc. While extremely hard passivation stacks employing silicon carbide (SiC) have been developed for these circuits, the capacitive electrodes may still become very badly damaged through use.

[0004] It would be desirable, therefore, to provide a mechanism for preventing damage to integrated circuits resulting from required contact with a sensor portion of the integrated circuit.

[0005] In capacitive sensor circuits where physical contact is required and excess pressure may be inadvertently applied to the sensor surface, aluminum is not sufficiently hard to provide "scratch" protection and may delaminate, causing circuit failure even if passivation integrity remains intact. Because hard passivation layers alone provide insufficient scratch resistance, all metallization levels within the sensor circuit between the surface and the active regions of the substrate are formed of a conductive material having a hardness greater than that of aluminum. The selected conductive material preferably has a hardness which is at least as great as the lowest hardness for any interlevel dielectric or passivation material employed. The selected conductive material is employed for each metallization level between the surface and the active regions, including contacts and vias, landing pads, interconnects, capacitive electrodes, and electrostatic discharge protection

lines. Tungsten is a suitable conductive material, for which existing processes may be substituted in place of aluminum metallization processes.

[0006] The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself however, as well as a preferred mode of use, and further objects and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

Figures 1A-1C depict various views of a sensor circuit employing scratch resistance in accordance with a preferred embodiment of the present invention;

Figure 2 is a graph showing the hardness of various materials and material combinations employed within a sensor circuit; and

Figure 3 depicts utilization of a hard conductive material within a sensor circuit for improved scratch resistance in accordance with a preferred embodiment of the present invention.

[0007] The following description details the structure, application and features of the present invention, but it will be understood by those of skill in the art that the scope of the invention is defined only by the issued claims, and not by any description herein. The process steps and structures described below do not form a complete process flow for manufacturing integrated circuits. The present invention can be practiced in conjunction with integrated circuit fabrication techniques currently used in the art, and only so much of the commonly practiced process steps are included as are necessary for an understanding of the present invention. The figures representing cross-sections of portions of an integrated circuit during fabrication are not drawn to scale, but instead are drawn so as to illustrate the important features of the invention.

[0008] With reference now to the figures, and in particular with reference to **Figures 1A through 1C**, various views of a sensor circuit employing scratch resistance in accordance with a preferred embodiment of the present invention are depicted. **Figure 1A** depicts a block diagram of the sensor circuit **102**, which is formed as an integrated circuit on a single die. The sensor circuit **102** and its operation are described more fully in commonly assigned, copending application serial no. 09/040,261, entitled "CAPACITIVE DISTANCE SENSOR" and filed May 9, 1998, which is incorporated herein by reference.

[0009] The portions of sensor circuit **102** relevant to the present invention include an array **104** of capacitive sensors for fingerprint acquisition by sensing distances between capacitive electrodes within the sensor array **104** and ridges and grooves on a finger placed in con-

tact with sensor array 104. Sensor circuit 102 also includes signal lines 106 and 108 and output bus 110. Signal line 106 connects I²C interface and control device 104, which provides a bidirectional communication protocol enabling sensor circuit 102 to communicate with a controller such as a microcontroller, with controller circuitry (not shown) external to sensor circuit 102. Signal line 108 is a synchronization line coupling sensor array 104 to the external controller circuit, providing synchronization signals allowing detected voltages representative of the capacitive value of individual capacitive electrodes within sensor array 104, and therefore representative of the distance between the capacitive electrode and the portion of the epidermal layer contacting sensor array 104 in the region of the capacitive electrode, to be properly interpreted by the external controller. Output bus 110 coupling an analog-to-digital (A/D) converter 114 to the external controller. A/D converter 114 processes analog voltage measurements received from sensor array 104 and generates digital representations recognized by the external controller as distance measurements of the analog measured voltages from individual capacitive electrodes within sensor array 104. A/D converter 114 transmits these digital signals to the external controller on output bus 110.

[0010] Figure 1B is a pictorial representation of the "front" side of sensor circuit 102; that is, Figure 1B depicts the major surface of the die 116 on which the active devices constituting sensor circuit 102 are formed. Sensor array 104 is located on the front side of die 116 and includes a plurality of cells 118, each containing one or more capacitive electrodes. Sensor array 104 in the exemplary embodiment contains square cells approximately 45-50 μm on a side, forming a 250 X 350 array of contiguous cells 118 within sensor array 104. Sensor array 104 is covered by a passivation material overlying the capacitive electrodes within each cell 118. Other active devices required to form sensor circuit 102 are formed below the capacitive electrodes.

[0011] Figure 1C is a cross-sectional detail of a sensor array cell as seen from a cross-section taken along section line A-A. Sensor circuit 102 within a sensor array cell includes one or more active areas, such as polysilicon electrodes 120 or source/drain region 122 within a substrate 124. A dielectric 126 overlies active areas 120, 122, with openings through which metal contacts 128 are formed to connect active regions 120, 122 with metal regions 130 (e.g., landing pads or interconnects) within the first metallization level. An intermetal dielectric 132 overlies metal regions 130 and dielectric 126, with openings therethrough in which are formed metal vias 134 connecting metal regions 130 to capacitive electrodes 136 overlying the interlevel dielectric 134.

[0012] Capacitive electrodes 136 are covered by a second intermetal dielectric 138, on which are formed electrostatic discharge (ESD) protection patterns 140. A

passivation layer 142, which may actually comprise multiple layers, covers the ESD protection lines 142 and forms the surface 144 which is contacted by the epidermal layer of the finger during fingerprint acquisition.

[0013] In the present invention, none of the metallization levels—contacts 128, metal regions 130, vias 134, capacitive electrodes 136, or ESD protection patterns 140—are formed of aluminum. A cause of "scratch" damage in capacitive sensor circuits of the type described above has been determined to be aluminum: the layer is too weak, and may delaminate, causing circuit failure, even if the passivation integrity is not violated. The hardness of various materials and material combinations is shown in the graph of Figure 2. The hardness of materials for which the graph label includes an asterisk ("*") were taken from literature references, while the other hardness values were determined experimentally.

[0014] As shown in Figure 2, silicon dioxide ("quartz," or simply "oxide"), which is commonly employed as an interlevel dielectric, has a hardness of slightly less than 10 gigaPascals (GPa). Silicon carbide (SiC), which is a suitable passivation material, and silicon together have an even greater hardness, comparable to that of diamond-like carbon (DLC). However aluminum, the most common metallization material, has a hardness much lower than quartz. The hardness of silicon carbide, a passivation material, and silicon, from which most substrates are formed, are much greater than that of aluminum. Since aluminum electrodes are typically between two such very hard layers, the tendency of aluminum to collapse and/or delaminate under sufficient pressure is not surprising.

[0015] A capacitive sensor circuit of the type described above typically includes a plurality of layer, including: silicon carbide and silicon nitride, which form a suitable passivation layer; silicon dioxide, a suitable interlevel dielectric; aluminum, the most commonly-employed metal for metallization levels; and silicon, the conventional material for an integrated circuit substrate. However, a sequence of layers of different materials is unlikely to have a total hardness significantly greater than that of the constituent material having the lowest hardness. Thus, micro scratch results within Figure 2 for the sequence of layers described above (SiC/SiN/SiO₂/Al/Si) demonstrate that the combined hardness is, as expected, not significantly greater than that of aluminum alone.

[0016] In the present invention, this problem is solved by employing a hard conductive material in place of aluminum for all metallization levels. Tungsten (W) has a suitable hardness, as illustrated in Figure 2 by micro scratch results for the sequence of layers described above with tungsten substituted for aluminum (i.e., SiC/SiN/SiO₂/W/Si). Other suitably hard conductive materials include copper (Cu) and titanium nitride (TiN), and perhaps conductive polysilicon. The hardness of the conductive material selected for the metalli-

zation levels should preferably exceeds the lowest hardness of any other material employed. In most structures, the material (other than aluminum) having the lowest hardness will commonly be the interlevel dielectric oxide. Any material having a hardness greater than that of aluminum, however, will provide better scratch resistance protection.

[0017] With reference now to **Figure 3**, utilization of a hard conductive material within a sensor circuit for improved scratch resistance in accordance with a preferred embodiment of the present invention is depicted. Capacitive electrodes **302** are connected to underlying conductive polysilicon structures **304**, which may be gate electrodes, source/drain contacts, or interconnects, through an interlevel dielectric **306** and a lower dielectric layer **308**. Within a sensor area **310** of the integrated circuit, to which physical contact with the sensor circuit is expected, the conductive regions **312** connecting capacitive electrodes **302** to polysilicon conductors **304**, together with the capacitive electrodes **302** themselves and ESD protection lines **314** within passivation **316**, are all formed of a conductive material having a hardness greater than that of aluminum. Tungsten is preferable since the hardness of tungsten provides suitable scratch resistance and known processes for forming tungsten contacts, vias, and interconnects may be readily substituted for aluminum metallization processes. Other metals for which processing techniques are now known or may be developed, such as copper, may also be employed if sufficiently hard.

[0018] Within the periphery and pad areas **318** and **320** of the capacitive circuit, which physical contact is neither expected nor necessary and where mechanical scratch protection may be built into the sensor circuit packaging, aluminum conductive regions may be employed to connect ESD protection lines **314** to underlying circuitry and for pads **322**. However, for simplicity in processing, tungsten may alternatively be employed for all metallization levels in all areas of the sensor circuit.

[0019] In the present invention, aluminum metallization within an integrated circuit is replaced by a conductive material having a greater hardness, resulting in improved "scratch" resistance for integrated circuit. This may be employed in any integrated circuit, but is especially useful in sensor array circuits employed for fingerprint or signature acquisition. Combined with hard passivation, the present invention improves the performance and lifetime of sensor circuits for which direct physical contact with a finger, stylus, or other object is required.

[0020] While the invention has been particularly shown and described with reference to a preferred embodiment, it will be understood by those skilled in the art that various changes in form and detail may be made therein without departing from the spirit and scope of the invention.

Claims

1. An integrated circuit structure, comprising:
 - a capacitive electrode;
 - a dielectric underlying the capacitive electrode;
 - and
 - an active region underlying the dielectric, wherein the capacitive electrode and each conductive region between the capacitive electrode and the active region are formed of a conductive material having a hardness greater than a hardness of aluminum.
2. The integrated circuit structure of claim 1, wherein the capacitive electrode and each conductive region between the capacitive electrode and the active region are formed of a conductive material having a hardness at least as great as a hardness of the dielectric.
3. The integrated circuit structure of claim 1, further comprising:
 - a passivation layer over the capacitive electrode, wherein the capacitive electrode and each conductive region between the capacitive electrode and the active region are formed of a conductive material having a hardness at least as great as a hardness of the passivation layer.
4. The integrated circuit structure of claim 1, wherein the capacitive electrode and each conductive region between the capacitive electrode and the active region are formed of tungsten.
5. The integrated circuit structure of claim 4, further comprising:
 - a tungsten via beneath the capacitive electrode.
6. The integrated circuit structure of claim 5, further comprising:
 - a tungsten interconnect beneath the via.
7. The integrated circuit structure of claim 6, further comprising: a tungsten contact between the interconnect and the active region.
8. The integrated circuit structure of claim 7, wherein the active region is a gate electrode.
9. An integrated circuit structure, comprising:
 - an active region;

a dielectric overlying the active region and having a contact opening therethrough;
 a tungsten contact within the contact opening;
 a tungsten metal region overlying the contact and a portion of the dielectric;
 an interlevel dielectric overlying the tungsten metal region and the dielectric and having an opening therethrough;
 a tungsten via within the opening through the interlevel dielectric; and
 a tungsten capacitive electrode overlying the tungsten via and a portion of the interlevel dielectric, wherein the capacitive electrode is electrically connected to the active region by the contact, the metal region, and the via.

10. The integrated circuit structure of claim 9, further comprising:

an oxide over the capacitive electrode and the interlevel dielectric adjacent the capacitive electrode;
 a passivation layer including a silicon nitride layer and a silicon carbide layer over the oxide; and
 tungsten ESD protection within the passivation layer.

11. An integrated circuit, comprising:

an array of capacitive electrodes in a central portion of the integrated circuit; and
 ESD protection devices and contact pads around a periphery of the integrated circuit, wherein the capacitive electrodes and every metallization region beneath the array of capacitive electrodes within the central portion of the integrated circuit is formed of a material having a hardness greater than aluminum while at least one metallization region beneath an ESD protection device or contact pad is formed of aluminum.

12. The integrated circuit of claim 11, wherein every metallization region within the central portion of the integrated circuit is formed of tungsten.

13. The integrated circuit of claim 12, further comprising:

tungsten ESD protection above and between capacitive electrodes within the array of capacitive electrodes and within the central portion of the integrated circuit, wherein each capacitive electrode within the array is formed of tungsten;
 tungsten vias beneath each capacitive electrode;

tungsten interconnects beneath each tungsten via;
 tungsten contacts beneath each tungsten interconnect; and
 active regions beneath each tungsten contact.

14. A method of forming a scratch resistant integrated circuit structure, comprising:

forming an active region;
 forming a dielectric overlying the active region; and
 forming a capacitive electrode overlying the dielectric, wherein the capacitive electrode and each conductive region between the capacitive electrode and the active region are formed of a conductive material having a hardness greater than a hardness of aluminum.

15. The method of claim 14, wherein the capacitive electrode and each conductive region between the capacitive electrode and the active region are formed of tungsten.

16. The method of claim 15, further comprising:

forming a tungsten via beneath the capacitive electrode.

17. The method of claim 16, further comprising:

forming a tungsten interconnect beneath the via.

18. The method of claim 17, further comprising:

forming a tungsten contact between the interconnect and the active region.

19. A method of forming an integrated circuit structure, comprising:

forming an active region;
 forming a dielectric overlying the active region and having a contact opening therethrough;
 forming a tungsten contact within the contact opening;
 forming a tungsten metal region overlying the contact and a portion of the dielectric;
 forming an interlevel dielectric overlying the tungsten metal region and the dielectric and having an opening therethrough;
 forming a tungsten via within the opening through the interlevel dielectric; and
 forming a tungsten capacitive electrode overlying the tungsten via and a portion of the interlevel dielectric, wherein the capacitive electrode is electrically connected to the active

region by the contact, the metal region, and the via.

20. A method of forming a scratch resistant integrated circuit structure, comprising:

5

forming a plurality of active regions;
forming a dielectric over the plurality active regions; and
forming an array of capacitive electrodes overlying the dielectric of a conductive material having a hardness at least as great as a hardness of the dielectric.

10

21. The method of claim 20 wherein the step of forming an array of capacitive electrodes overlying the dielectric of a conductive material having a hardness at least as great as a hardness of the dielectric further comprises:

15

forming the array of capacitive electrodes of a conductive material having a hardness at least as great as a hardness of a passivation layer overlying the array of conductive electrodes.

20

25

22. The method of claim 20 wherein the step of forming an array of capacitive electrodes overlying the dielectric of a conductive material having a hardness at least as great as a hardness of the dielectric further comprises:

30

forming the array of capacitive electrodes of tungsten.

23. The method of claim 20 further comprising:

35

forming each metallization region between the array of capacitive electrodes and the plurality of active regions of a conductive material having a hardness at least as great as the hardness of the dielectric.
